to

Concepts of Programming Languages
Sixth Edition
R.W. Sebesta
Preface

Changes to the Sixth Edition

The goals, overall structure, and approach of this sixth edition of Concepts of Programming Languages remain the same as those of the five earlier editions. The principal goal is to provide the reader with the tools necessary for the critical evaluation of existing and future programming languages. An additional goal is to prepare the reader for the study of compiler design. There were several sources of our motivations for the changes in the sixth edition. First, to maintain the currency of the material, much of the discussion of older programming languages has been removed. In its place is material on newer languages. Especially interesting historical information on older programming languages has been retained but placed in historical side boxes. Second, the material has been updated to reflect the fact that most students now come to this course with a basic understanding of object-oriented programming. We shortened the discussion of basics and expanded the discussion of advanced topics.

Third, reviewer comments have prompted several changes. For example, the material on functional programming languages has been reorganized and strengthened. Also, we have added a programming exercises section at the end of most chapters to give students experience with the concepts described in the book and to make the concepts more realistic and appealing. The book now has a new supplement: a companion Web site with a few small language manuals, interactive quizzes for students, and additional programming projects. Finally, interviews with the designers of recent languages that have achieved widespread use appear in several places in the book. These show the human side of language development.

Four specific changes distinguish the sixth edition text from its predecessor. First, the material on implementing subprograms has been condensed, largely because the virtual disappearance of Pascal and Modula-2, as well as the shrinking usage of Ada, has made the implementation of nested subprograms with static scoping less important. All of the relevant Pascal examples were rewritten in Ada. Second, Chapter 14 has been expanded to cover both exception handling and event handling. This change was motivated by the great increase in interest and importance of event handling that has come with the wide use of interactive Web documents. Third, the introduction to Smalltalk has been eliminated because we believe the syntactic details of Smalltalk are no longer relevant to the material of the book. Fourth, there are numerous significant changes motivated by the aging of existing programming languages and the emergence of new programming languages. There is now little mention of Modula-2, Pascal, and the ALGOLs. Also, the coverage of Ada and Fortran has been whittled down to the more interesting of their features that do not appear in other popular languages. New material on JavaScript, PHP, and C# has been added where appropriate. Finally, most chapters now include a new section, Programming Exercises.

The Vision

This book describes the fundamental concepts of programming languages by discussing the design issues of the various language constructs, examining the design choices for these constructs in some of the most common languages, and critically comparing design alternatives.

Any serious study of programming languages requires an examination of some related topics, among which are formal methods of describing the syntax and semantics of programming languages, which are covered in Chapter 3. Also, implementation techniques for various language constructs must be considered: Lexical and syntax analysis are discussed in Chapter 4, and implementation of subprogram linkage is covered in Chapter 10. Implementation of some other language constructs is discussed in various other parts of the book.
The following paragraphs outline the contents of the sixth edition.

**Chapter Outlines**

Chapter 1 begins with a rationale for studying programming languages. It then discusses the criteria used for evaluating programming languages and language constructs. The primary influences on language design, common design tradeoffs, and the basic approaches to implementation are also examined.

Chapter 2 outlines the evolution of most of the important languages discussed in this book. Although no language is described completely, the origins, purposes, and contributions of each are discussed. This historical overview is valuable because it provides the background necessary to understanding the practical and theoretical basis for contemporary language design. It also motivates further study of language design and evaluation. In addition, because none of the remainder of the book depends on Chapter 2, it can be read on its own, independent of the other chapters.

Chapter 3 describes the primary formal method for describing the syntax of programming language, BNF. This is followed by a description of attribute grammars, which describe both the syntax and static semantics of languages. The difficult task of semantic description is then explored, including brief introductions to the three most common methods: operational, axiomatic, and denotational semantics.

Chapter 4 introduces lexical and syntax analysis. This chapter is targeted to those colleges that no longer require a compiler design course in their curricula. Like Chapter 2, this chapter stands alone and can be read independently of the rest of the book.

Chapters 5 through 14 describe in detail the design issues for the primary constructs of the imperative languages. In each case, the design choices for several example languages are presented and evaluated. Specifically, Chapter 5 covers the many characteristics of variables, Chapter 6 covers data types, and Chapter 7 explains expressions and assignment statements. Chapter 8 describes control statements, Chapters 9 and 10 discuss subprograms and their implementation. Chapter 11 examines data abstraction facilities. Chapter 12 provides an in-depth discussion of language features that support object-oriented programming (inheritance and dynamic method binding), Chapter 13 discusses concurrent program units, and Chapter 14 is about exception handling and event handling.

The last two chapters (15 and 16) describe two of the most important alternative programming paradigms: functional programming and logic programming. Chapter 15 presents an introduction to Scheme, including descriptions of some of its primitive functions, special forms, and functional forms, as well as some examples of simple functions written in Scheme. Brief introductions to COMMON LISP, ML, and Haskell are given to illustrate some different kinds of functional language. Chapter 16 introduces logic programming and the logic programming language, Prolog.

**To the Instructor**

In the junior-level programming language course at the University of Colorado at Colorado Springs, the book is used as follows: We typically cover Chapters 1 and 3 in detail, and though students find it interesting and beneficial reading, Chapter 2 receives little lecture time due to its lack of hard technical content. Because no material in subsequent chapters depends on Chapter 2, as noted earlier, it can be skipped entirely, and because we require a course in compiler design, Chapter 4 is not covered.

Chapters 5 through 9 should be relatively easy for students with extensive programming experience in C++, Java, or C#. Chapters 10 through 14 are more challenging and require more detailed lectures.

Chapters 15 and 16 are entirely new to most students at the junior level. Ideally, language processors for
Scheme and Prolog should be available for students required to learn the material in these chapters. Sufficient material is included to allow students to dabble with some simple programs.

Undergraduate courses will probably not be able to cover all of the last two chapters in detail. Graduate courses, however, by skipping over parts of the early chapters on imperative languages, will be able to completely discuss the nonimperative languages.

**Supplemental Materials**

The following supplements are available to all readers of this book at www.aw.com/cssupport:

- A set of lecture notes slides. These slides are in the form of Microsoft PowerPoint source files, one for each of the chapters of the book.
- PowerPoint slides of all the figures in the book, should you wish to create your own lecture notes.
- A companion web site. With the sixth edition we are introducing a brand-new supplements package for students. To reinforce learning in the classroom, to assist with the hands-on lab component of this course, and/or to facilitate students in a distance learning situation, the edition will be accompanied by a comprehensive web site with the following content:
  1. Mini manuals (approximately 100-page tutorials) on a handful of languages. These will assume that the student knows how to program in some other language, giving the student enough information to complete the chapter materials in each language. Currently manuals are planned in C++, C, Java, and C#.
  2. Lab projects. A series of lab projects will be defined for each concept taught in the book. The solutions will be available exclusively to those teaching a course.
  3. Self-grading review exercises. Using the Addison-Wesley software engine, students can complete a series of multiple-choice and fill-in-the-blank exercises to check their understanding of the chapter just read.

Solutions to many of the problem sets are available only to qualified instructors. Please contact your local Addison-Wesley sales representative, or send e-mail to aw.cse@aw.com, for information about how to access them.

**Language Processor Availability**

Processors for and information about some of the programming languages discussed in this book can be found at the following web sites:

<table>
<thead>
<tr>
<th>Language</th>
<th>Web Site</th>
</tr>
</thead>
<tbody>
<tr>
<td>C#</td>
<td><a href="http://microsoft.com">http://microsoft.com</a></td>
</tr>
<tr>

</tbody>
</table>

JavaScript is included in virtually all browsers; PHP is included in virtually all Web servers.

All this information is also included on the companion web site.

**Acknowledgements**

The suggestions from outstanding reviewers contributed greatly to this book's present form. In alphabetical order, they are:

Charles Dana, California Polytechnic State University, San Luis Obispo
Eric Joanis, University of Toronto
Donald H. Kraft, Louisiana State University
Numerous other people provided input for the previous editions of Concepts of Programming Languages at various stages of its development. All of their comments were useful and greatly appreciated. In alphabetical order, they are: Vicki Allan, Henry Bauer, Carter Bays, Manuel E. Bermudez, Peter Brouwer, Margaret Burnett, Paosheng Chang, John Crenshaw, Barbara Ann Griem, Mary Lou Haag, Eileen Head, Ralph C. Hilzer, Hikyoo Koh, Jiang B. Liu, Meiliu Lu, Jon Mauney, Bruce R. Maxim, Robert McCoard, Michael G. Murphy, Andrew Oldroyd, Rebecca Parsons, Jeffery Popyack, Steven Rapkin, Hamilton Richard, Tom Sager, Joseph Schell, Mary Louise Soffa and John M. Weiss.

Maite Suarez-Rivas, Editor, Katherine Harutunian, Project Editor, and Juliet Silveri, Production Supervisor at Addison-Wesley, and Daniel Rausch at Argosy, all deserve my gratitude for their efforts to produce the sixth edition quickly, as well as help make it significantly more complete than the fifth.

Finally, I thank my children, Jake and Darcie, for their patience in enduring my absence from them throughout the endless hours of effort I invested in writing the six editions of this book.

About the Author

Robert Sebesta is an Associate Professor in the Computer Science Department at the University of Colorado, Colorado Springs. Professor Sebesta received a B.S. in applied mathematics from the University of Colorado in Boulder and his M.S. and Ph.D. degrees in Computer Science from the Pennsylvania State University. He has taught computer science for over 30 years. His professional interests are the design and evaluation of programming languages, compiler design, and software testing methods and tools. He is a member of the ACM and the IEEE Computer Society.

Chapter 2 Evolution of the Major Imperative Programming Languages

2.1 Zuse's Plankalkül
   2.1.1 Historical Background
   2.1.2 Language Overview

2.2 Minimal Hardware Programming: Pseudocodes
   2.2.1 Short Code
   2.2.2 Speedcoding
   2.2.3 The UNIVAC "Compiling" System
   2.2.4 Related Work

2.3 The IBM 704 and Fortran
   2.3.1 Historical Background
   2.3.2 Design Process
   2.3.3 Fortran I Overview
   2.3.4 Fortran II
   2.3.5 Fortran IV, Fortran 77, 90, and 95
   2.3.6 Evaluation

2.4 Functional Programming: LISP
   2.4.1 The Beginnings of Artificial Intelligence and List Processing
   2.4.2 LISP Design Process
   2.4.3 Language Overview
   2.4.3.1 Data Structures
   2.4.3.2 Processes in Functional Programming
   2.4.3.3 The Syntax of LISP
   2.4.4 Evaluation
   2.4.5 Two Descendants of LISP
   2.4.5.1 Scheme
   2.4.5.2 COMMON LISP
   2.4.6 Related Languages

2.5 The First Step Toward Sophistication: ALGOL 60
   2.5.1 Historical Background
   2.5.2 Early Design Process
   2.5.3 ALGOL 58 Overview
   2.5.4 Reception of the ALGOL 58 Report
   2.5.5 ALGOL 60 Design Process
   2.5.6 ALGOL 60 Overview
   2.5.7 ALGOL 60 Evaluation

2.6 Computerizing Business Records: COBOL
   2.6.1 Historical Background
   2.6.2 FLOW-MATIC
   2.6.3 COBOL Design Process
   2.6.4 Evaluation

2.7 The Beginnings of Timesharing: BASIC

# Chapter 3 Describing Syntax and Semantics

3.1 Introduction 114
3.2 The General Problem of Describing Syntax 115
3.2.1 Language Recognizers 116
3.2.2 Language Generators 116
3.3 Formal Methods of Describing Syntax 117
3.3.1 Backus-Naur Form and Context-Free Grammars 117
3.3.1.1 Context-Free Grammars 117
3.3.1.2 Origins of Backus-Naur Form 117
3.3.1.3 Fundamentals 118
3.3.1.4 Describing Lists 119
3.3.1.5 Grammars and Derivations 119
3.3.1.6 Parse Trees 121
3.3.1.7 Ambiguity 122
3.3.1.8 Operator Precedence 123
3.3.1.9 Associativity of Operators 125
3.3.1.10 An Unambiguous Grammar for if-then-else 126
3.3.2 Extended BNF 128
3.3.3 Grammars and Recognizers 130
3.4 Attribute Grammars 130
3.4.1 Static Semantics 130
3.4.2 Basic Concepts 131
3.4.3 Attribute Grammars Defined 131
3.4.4 Intrinsic Attributes 132
3.4.5 Example Attribute Grammars 132
3.4.6 Computing Attribute Values 134
3.4.7 Evaluation 136
3.5 Describing the Meanings of Programs: Dynamic Semantics 136
3.5.1 Operational Semantics 137
3.5.1.1 The Basic Process 137
3.5.1.2 Evaluation 139
3.5.2 Axiomatic Semantics 139
3.5.2.1 Assertions 139
3.5.2.2 Weakest Preconditions 140
3.5.2.3 Assignment Statements 141
3.5.2.4 Sequences 143
3.5.2.5 Selection 144
3.5.2.6 Logical Pretest Loops 144
3.5.2.7 Evaluation 150
3.5.3 Denotational Semantics 150
3.5.3.1 Two Simple Examples 150
3.5.3.2 The State of a Program 152
3.5.3.3 Expressions 153
3.5.3.4 Assignment Statements 154
Chapter 11  Data Abstraction

11.1  The Concept of Abstraction 428
11.2  Introduction to Data Abstraction 429
11.2.1  Floating-Point as an Abstract Data Type 429
11.2.2  User-Defined Abstract Data Types 430
11.2.3  An Example 431
11.4  Design Issues for Abstract Data Types 432
11.4  Language Examples 433
11.4.1  Abstract Data Types in Ada 433
11.4.1.1  Encapsulation 433
11.4.1.2  Information Hiding 433
11.4.1.3  An Example 437
11.4.2  Abstract Data Types in C++ 439
11.4.2.1  Encapsulation 439
11.4.2.2  Information Hiding 439
11.4.2.3  An Example 440
11.4.2.4  Evaluation 442
11.4.3  Abstract Data Types in Java 442
11.4.4  Abstract Data Types in C# 443
11.5  Parameterized Abstract Data Types 445
11.5.1  Ada 445
11.5.2  C++ 446
11.6  Encapsulation Construct 448
11.6.1  Introduction 448
11.6.2  Nested Subprograms 448
11.6.3  Encapsulation in C 448
11.6.4  Encapsulation in C++ 449
11.6.5  Ada Packages 450
11.6.6  C# Assemblies 450
11.7  Naming Encapsulations 451
11.7.1  C++ Namespaces 451
11.7.2  Java Packages 452
11.7.3  Ada Packages 453

Summary 453
Review Questions 454

Programming Exercises 456

Chapter 12  Support for Object-Oriented Programming

12.1  Introduction 458
12.2  Object-Oriented Programming 458
12.2.1  Introduction 458
12.2.2  Inheritance 459
12.2.3  Polymorphism and Dynamic Binding 460
12.3  Design Issues for Object-Oriented Language 461
12.3.1  The Exclusivity of Objects 461
Chapter 13

13.3 Semaphores
13.3.1 Introduction 503
13.3.2 Cooperation Synchronization 504
13.3.3 Competition Synchronization 506
13.3.4 Evaluation 508

13.4 Monitors
13.4.1 Introduction 508
13.4.2 Cooperation Synchronization 509
13.4.3 Competition Synchronization 510
13.4.4 Evaluation 513

13.5 Message Passing
13.5.1 Introduction 513
13.5.2 The Concept of Synchronous Message Passing 513
13.5.3 The Ada Synchronous Message-Passing Model 514
13.5.4 Cooperation Synchronization 519
13.5.5 Competition Synchronization 520
13.5.6 Task Termination 521
13.5.7 Priorities 521
13.5.8 Binary Semaphores 522
13.5.9 Protected Objects 522
13.5.10 Asynchronous Message Passing 524
13.5.11 Evaluation 524

13.6 Java Threads
13.6.1 The Thread Class 525
13.6.2 Priorities 527
13.6.3 Competition Synchronization 528
13.6.4 Cooperation Synchronization 528
13.6.5 Evaluation 532

13.7 C# Threads 532
13.7.1 Basic Thread Operations 532
13.7.2 Synchronizing Threads 533
13.7.3 Evaluation 534

13.8 Statement-Level Concurrency 534
13.8.1 High-Performance Fortran 534

Chapter 14 Exception Handling and Event Handling

14.1 Introduction to Exception Handling
14.1.1 Basic Concepts 543
14.1.2 Design Issues 545

14.2 Exception Handling in Ada
14.2.1 Exception Handlers 548
14.2.2 Binding Exceptions to Handlers 549
14.2.3 Continuation 550
14.2.4 Other Design Choices 551
14.2.5 An Example 552
14.2.6 Evaluation 554

14.3 Exception Handling in C++ 554
Chapter 16 Logic Programming Languages

16.1 Introduction 618
16.2 A Brief Introduction to Predicate Calculus 618
16.2.1 Propositions 619
16.2.2 Clausal Form 621
16.3 Predicate Calculus and Proving Theorems 621
16.4 An Overview of Logic Programming 624
16.5 The Origins of Prolog 625
16.6 The Basic Elements of Prolog 626
16.6.1 Terms 626
16.6.2 Fact Statements 627

Review Questions 649
Problem Set 649
Programming Exercises 650
Answers to Selected Problems

Chapter 1

Problem Set:

3. Some arguments for having a single language for all programming domains are: It would dramatically cut the costs of programming training and compiler purchase and maintenance; it would simplify programmer recruiting and justify the development of numerous language dependent software development aids.

4. Some arguments against having a single language for all programming domains are: The language would necessarily be huge and complex; compilers would be expensive and costly to maintain; the language would probably not be very good for any programming domain, either in compiler efficiency or in the efficiency of the code it generated.

5. One possibility is wordiness. In some languages, a great deal of text is required for even simple complete programs. For example, COBOL is a very wordy language. In Ada, programs require a lot of duplication of declarations. Wordiness is usually considered a disadvantage, because it slows program creation, takes more file space for the source programs, and can cause programs to be more difficult to read.

7. The argument for using the right brace to close all compounds is simplicity—a right brace always terminates a compound. The argument against it is that when you see a right brace in a program, the location of its matching left brace is not always obvious, in part because all multiple-statement control constructs end with a right brace.

8. The reasons why a language would distinguish between uppercase and lowercase in its identifiers are: (1) So that variable identifiers may look different than identifiers that are names for constants, such as the convention of using uppercase for constant names and using lowercase for variable names in C, and (2) so that catenated words as names can have their first letter distinguished, as in TotalWords. (I think it is better to include a connector, such as underscore.) The primary reason why a language would not distinguish between uppercase and lowercase in identifiers is it makes programs less readable, because words that look very similar are actually completely different, such as SUM and Sum.

10. One of the main arguments is that regardless of the cost of hardware, it is not free. Why write a program that executes slower than is necessary. Furthermore, the difference between a well-written efficient program and one that is poorly written can be a factor of two or three. In many other fields of endeavor, the difference between a good job and a poor job may be 10 or 20 percent. In programming, the difference is much greater.

15. The use of type declaration statements for simple scalar variables may have very little effect on the readability of programs. If a language has no type declarations at all, it may be an aid to readability, because regardless of where a variable is seen in the program text, its type can be determined without looking elsewhere. Unfortunately, most languages that allow implicitly declared variables also include explicit declarations. In a program in such a language, the declaration of a variable must be found before the reader can determine the type of that variable when it is used in the program.
18. The main disadvantage of using paired delimiters for comments is that it results in diminished reliability. It is easy to inadvertently leave off the final delimiter, which extends the comment to the end of the next comment, effectively removing code from the program. The advantage of paired delimiters is that you can comment out areas of a program. The disadvantage of using only beginning delimiters is that they must be repeated on every line of a block of comments. This can be tedious and therefore error-prone. The advantage is that you cannot make the mistake of forgetting the closing delimiter.

Chapter 2

Problem Set:

6. Because of the simple syntax of LISP, few syntax errors occur in LISP programs. Unmatched parentheses is the most common mistake.

7. The main reason why imperative features were put in LISP was to increase its execution efficiency.

10. The main motivation for the development of PL/I was to provide a single tool for computer centers that must support both scientific and commercial applications. IBM believed that the needs of the two classes of applications were merging, at least to some degree. They felt that the simplest solution for a provider of systems, both hardware and software, was to furnish a single hardware system running a single programming language that served both scientific and commercial applications.

11. IBM was, for the most part, incorrect in its view of the future of the uses of computers, at least as far as languages are concerned. Commercial applications are nearly all done in languages that are specifically designed for them. Likewise for scientific applications. On the other hand, the IBM design of the 360 line of computers was a great success--it still dominates the area of computers between supercomputers and minicomputers. Furthermore, 360 series computers and their descendants have been widely used for both scientific and commercial applications. These applications have been done, in large part, in FORTRAN and COBOL.

14. The argument for typeless languages is their great flexibility for the programmer. Literally any storage location can be used to store any type value. This is useful for very low-level languages used for systems programming. The drawback is that type checking is impossible, so that it is entirely the programmer's responsibility to insure that expressions and assignments are correct.

18. A good deal of restraint must be used in revising programming languages. The greatest danger is that the revision process will continually add new features, so that the language grows more and more complex. Compounding the problem is the reluctance, because of existing software, to remove obsolete features.

Chapter 3
Instructor's Note:

In the program proof on page 149, there is a statement that may not be clear to all, specifically, \((n + 1) \times \ldots \times n = 1\). The justification of this statement is as follows:

Consider the following expression:

\[(\text{count} + 1) \times (\text{count} + 2) \times \ldots \times n\]

The former expression states that when \(\text{count}\) is equal to \(n\), the value of the later expression is 1. Multiply the later expression by the quotient:

\[
\frac{(1 \times 2 \times \ldots \times \text{count})}{(1 \times 2 \times \ldots \times \text{count})}
\]

whose value is 1, to get

\[
\frac{(1 \times 2 \times \ldots \times \text{count} \times (\text{count} + 1) \times (\text{count} + 2) \times \ldots \times n)}{(1 \times 2 \times \ldots \times \text{count})}
\]

The numerator of this expressions is \(n!\). The denominator is \(\text{count}\!\!.\!\!.\!\!.\!)\). If \(\text{count}\) is equal to \(n\), the value of the quotient is

\[
\frac{n!}{n!}
\]

or 1, which is what we were trying to show.

Problem Set:

2a. \(<\text{class\_head}>\) ? {<modifier>} \text{class} <id> [\text{extends} class_name]

[\text{implements} <interface_name> [, <interface_name>]]

<modifier> ? \text{public} | \text{abstract} | \text{final}

2c. \(<\text{switch\_stmt}>\) ? \text{switch} ( <expr> ) {\text{case} <\text{literal}> : <\text{stmt\_list}>}

{\text{case} <\text{literal}> : <\text{stmt\_list}> } [\text{default} : <\text{stmt\_list}> ]

3. \(<\text{assign}>\) ? <id> = <expr>

<id> ? A | B | C

<expr> ? <expr> * <term>

| <term>

<term> ? <factor> + <term>

| <factor>

<factor> ? ( <expr> )
6.

(a) \(\text{assign} \Rightarrow \text{id} = \text{expr}\)

\[
\text{\Rightarrow A = expr} \\
\text{\Rightarrow A = id} \times \text{expr} \\
\text{\Rightarrow A = A} \times \text{expr} \\
\text{\Rightarrow A = A} \times (\text{expr}) \\
\text{\Rightarrow A = A} \times (\text{id} + \text{expr}) \\
\text{\Rightarrow A = A} \times (B + \text{expr}) \\
\text{\Rightarrow A = A} \times (B + (\text{id} \times \text{expr})) \\
\text{\Rightarrow A = A} \times (B + (C \times \text{expr})) \\
\text{\Rightarrow A = A} \times (B + (C \times id)) \\
\text{\Rightarrow A = A} \times (B + (C \times A))
\]
7.
(a) \( <assign> \Rightarrow <id> = <expr> \)

\[ \Rightarrow A = <expr> \]

\[ \Rightarrow A = <term> \]

\[ \Rightarrow A = <factor> * <term> \]

\[ \Rightarrow A = ( <expr> ) * <term> \]

\[ \Rightarrow A = ( <expr> + <term> ) * <term> \]

\[ \Rightarrow A = ( <term> + <term> ) * <term> \]

\[ \Rightarrow A = ( <factor> + <term> ) * <term> \]
=> A = ( <id> + <term> ) * <term>

=> A = ( A + <term> ) * <term>

=> A = ( A + <factor> ) * <term>

=> A = ( A + <id> ) * <term>

=> A = ( A + B ) * <term>

=> A = ( A + B ) * <factor>

=> A = ( A + B ) * <id>

=> A = ( A + B ) * C

```
<assign>
  <id> := <expr>

  A = <term>

        <factor> * <term>

        ( <expr> ) <factor>

        <expr> + <term> <id>

        <term> <factor> C

        <factor> <id>

        <id> B

        A
```
8. The following two distinct parse tree for the same string prove that the grammar is ambiguous.

```
<S>   <S>
|     |
|     |
<A>   <A>
|     |
|     |
<A>   <A>
|     |
|     |
<A>   <A>
|     |
|     |
a   b   c
```

9. Assume that the unary operators can precede any operand. Replace the rule

```
<factor> ? <id>
```

with

```
<factor> ? <id>
```

10. One or more a's followed by one or more b's followed by one or more c's.

13. S ? a S b | a b

14.

```
S
|   |
|   |
A    S
|   |
|   |
B    A
|   |
|   |
C    B
|   |
|   |
a   a
```

```
S
|   |
|   |
A    S
|   |
|   |
B    A
|   |
|   |
C    B
|   |
a   a
```

```
S
|   |
|   |
A    S
|   |
|   |
B    A
|   |
|   |
C    B
|   |
a   a
```
16. `<assign> ? <id> = <expr>`
    `<id> ? A | B | C`
    `<expr> ? <expr> (+ | -) <expr>`
        | (<expr>)
        | <id>

18.
(a) (Pascal `repeat`) We assume that the logic expression is a single relational expression.
    ```
    loop: ...
    ...
    if <relational_expression> goto out
    goto loop
    out: ...
    ```

(b) (Ada `for`) `for I in first .. last loop`
    ```
    I = first
    loop: if I < last goto out
    ...
    I = I + 1
    goto loop
    out:...
    ```

(c) (Fortran Do)
    ```
    K = start
    loop: if K > end goto out
    ```
\[ K = K + \text{step} \]
\[ \text{goto loop} \]
\[ \text{out: } \ldots \]

\begin{enumerate}
\item (C \textbf{for}) \textbf{for} (expr1; expr2; expr3) ...
  \begin{itemize}
  \item evaluate(expr1)
  \item loop: control = evaluate(expr2)
  \item if control == 0 goto out
  \item evaluate(expr3)
  \item goto loop
  \item out: \ldots
  \end{itemize}
\end{enumerate}

19.
\begin{enumerate}
\item (a) \[ a = 2 \times (b - 1) - 1 \quad \{a > 0\} \]
  \begin{itemize}
  \item \[ 2 \times (b - 1) - 1 > 0 \]
  \item \[ 2 \times b - 2 - 1 > 0 \]
  \item \[ 2 \times b > 3 \]
  \item \[ b > 3 / 2 \]
  \end{itemize}
\item (b) \[ b = (c + 10) / 3 \quad \{b > 6\} \]
  \begin{itemize}
  \item \[ (c + 10) / 3 > 6 \]
  \item \[ c + 10 > 18 \]
  \item \[ c > 8 \]
  \end{itemize}
\item (c) \[ a = a + 2 \times b - 1 \quad \{a > 1\} \]
\end{enumerate}
\( a + 2b - 1 > 1 \)
\( 2b > 2 - a \)
\( b > 1 - a/2 \)

(d) \( x = 2y + x - 1 \{x > 11\} \)
\( 2y + x - 1 > 11 \)
\( 2y + x > 12 \)

20.
(a) \( a = 2b + 1 \)
\( b = a - 3 \{b < 0\} \)
\( a - 3 < 0 \)
\( a < 3 \)

Now, we have:
\( a = 2b + 1 \{a < 3\} \)
\( 2b + 1 < 3 \)
\( 2b + 1 < 3 \)
\( 2b < 2 \)
\( b < 1 \)

(b) \( a = 3(2b + a); \)
\( b = 2a - 1 \{b > 5\} \)
\( 2a - 1 > 5 \)
\( 2a > 6 \)
\( a > 3 \)
Now we have:

\[ a = 3 \times (2 \times b + a) \{a > 3\} \]
\[ 3 \times (2 \times b + a) > 3 \]
\[ 6 \times b + 3 \times a > 3 \]
\[ 2 \times b + a > 1 \]
\[ n > (1 - a) / 2 \]

21a. \( M_p \) (for var in init_expr .. final_expr loop L end loop, s) \( \triangleq \)

if \( \text{VARMAP}(i, s) = \text{undef} \) for var or some i in init_expr or final_expr

then \text{error}

else if \( M_c(\text{init_expr}, s) > M_c(\text{final_expr}, s) \)

then s

else \( M_l(\text{while init_expr} - 1 \leq \text{final_expr} \text{ do L, } M_a(\text{var} := \text{init_expr} + 1, s)) \)

21b. \( M_r \) (repeat L until B) \( \triangleq \)

if \( M_b(B, s) = \text{undef} \)

then \text{error}

else if \( M_{sf}(L, s) = \text{error} \)

then \text{error}

else if \( M_b(B, s) = \text{true} \)

then \( M_{sf}(L, s) \)

else \( M_r(\text{repeat L until B, } M_{sf}(L, s)) \)

21c. \( M_b(B, s) \triangleq \) if \( \text{VARMAP}(i, s) = \text{undef} \) for some i in B
then error
else B', where B' is the result of
evaluating B after setting each
variable i in B to VARMAP(i, s)

21d. \( M_c(\text{for (expr1; expr2; expr3) L, s}) \)

if VARMAP (i, s) = \text{undef} for some i in expr1, expr2, expr3, or L
then error
else if \( M_c(\text{expr2, } M_c(\text{expr1, s})) = 0 \)
then s
else \( M_{\text{help}}(\text{expr2, expr3, L, s}) \)

\( M_{\text{help}}(\text{expr2, expr3, L, s}) \)

if VARMAP (i, s) = \text{undef} for some i in expr2, expr3, or L
then error
else
if \( M_{\text{sl}}(\text{L, s}) = \text{error} \)
then s
else \( M_{\text{help}}(\text{expr2, expr3, L, } M_{\text{sl}}(\text{L, } M_c(\text{expr3, s}))) \)

22. The value of an intrinsic attribute is supplied from outside the attribute evaluation process, usually from the lexical analyzer. A value of a synthesized attribute is computed by an attribute evaluation function.

23. Replace the second semantic rule with:

\(<\text{var}\>[2].\text{env} \ ? \ <\text{expr}\>.\text{env} \)
\(<\text{var}\>[3].\text{env} \ ? \ <\text{expr}\>.\text{env} \)
\(<\text{expr}\>.\text{actual_type} \ ? \ <\text{var}\>[2].\text{actual_type} \)
predicate: \(<\text{var}\>[2].\text{actual_type} = <\text{var}\>[3].\text{actual_type} \)
Chapter 4

Problem Set:

1. 
   (a) FIRST(aB) = \{a\}, FIRST(b) = \{b\}, FIRST(cBB) = \{c\}, Passes the test
   (b) FIRST(aB) = \{a\}, FIRST(bA) = \{b\}, FIRST(aBb) = \{a\}, Fails the test
   (c) FIRST(aaA) = \{a\}, FIRST(b) = \{b\}, FIRST(caB) = \{c\}, Passes the test

3.

**Programming Exercises:**

1. Every arc in this graph is assumed to have `addChar` attached. Assume we get here only if `charClass` is `SLASH`.

```
/   *   
\   |   /   *
```

33
3. int getComment() {
    getChar();
    /* The slash state */
    if (charClass != AST)
        return SLASH_CODE;
    else {
        /* The com state-end state loop */
        do {
            getChar();
        } while (charClass != AST)
        getChar();
        } while (charClass != SLASH);
        return COMMENT;
    }

Chapter 5

Problem Set:

2. The advantage of a typeless language is flexibility; any variable can be used for any type values. The disadvantage is poor reliability due to the ease with which type errors can be made, coupled with the impossibility of type checking detecting them.

3. This is a good idea. It adds immensely to the readability of programs. Furthermore, aliasing can be minimized by enforcing programming standards that disallow access to the array in any executable statements. The alternative to this aliasing would be to pass many parameters, which is a highly inefficient process.
5. Implicit heap-dynamic variables acquire types only when assigned values, which must be at runtime. Therefore, these variables are always dynamically bound to types.

6. Suppose that a Fortran subroutine is used to implement a data structure as an abstraction. In this situation, it is essential that the structure persist between calls to the managing subroutine.

8.

(a) i. Sub1
   ii. Sub1
   iii. Main

(b) i. Sub1
   ii. Sub1
   iii. Sub1

9. Static scoping: \( x = 5 \).
   Dynamic scoping: \( x = 10 \)

10. | Variable | Where Declared |
     |         |              |
     | In Sub1: |              |

(e) c, d, e fun2
   f fun3
Chapter 6

Problem Set:

1. Boolean variables stored as single bits are very space efficient, but on most computers access to them is slower than if they were stored as bytes.

2. Integer values stored in decimal waste storage in binary memory computers, simply as a result of the fact that it takes four binary bits to store a single decimal digit, but those four bits are capable of storing 16 different values. Therefore, the ability to store six out of every 16 possible values is wasted. Numeric values can be stored efficiently on binary memory
computers only in number bases that are multiples of 2. If humans had developed a number of fingers that was a power of 2, these kinds of problems would not occur.

6. When implicit dereferencing of pointers occurs only in certain contexts, it makes the language slightly less orthogonal. The context of the reference to the pointer determines its meaning. This detracts from the readability of the language and makes it slightly more difficult to learn.

7. The only justification for the \( \text{->} \) operator in C and C++ is writability. It is slightly easier to write \( p \rightarrow q \) than \( (*p).q \).

8. The advantage of having a separate construct for unions is that it clearly shows that unions are different from records. The disadvantages are that it requires an additional reserved word and that unions are often separately defined but included in records, thereby complicating the program that uses them.

9. Let the subscript ranges of the three dimensions be named \( \min(1) \), \( \min(2) \), \( \min(3) \), \( \max(1) \), \( \max(2) \), and \( \max(3) \). Let the sizes of the subscript ranges be \( \text{size}(1) \), \( \text{size}(2) \), and \( \text{size}(3) \). Assume the element size is 1.

Row Major Order:

\[
\text{location}(a[i,j,k]) = (\text{address of } a[\min(1),\min(2),\min(3)]) + ((i-\min(1))\times\text{size}(3) + (j-\min(2))\times\text{size}(2) + (k-\min(3))
\]

Column Major Order:

\[
\text{location}(a[i,j,k]) = (\text{address of } a[\min(1),\min(2),\min(3)]) + ((k-\min(3))\times\text{size}(1) + (j-\min(2))\times\text{size}(2) + (i-\min(1))
\]

10. The advantage of this scheme is that accesses that are done in order of the rows can be made very fast; once the pointer to a row is gotten, all of the elements of the row can be fetched very quickly. If, however, the elements of a matrix must be accessed in column order, these accesses will be much slower; every access requires the fetch of a row pointer and an address computation from there. Note that this access technique was devised to allow multidimensional array rows to be segments in a virtual storage management technique. Using this method, multidimensional arrays could be stored and manipulated that are much larger than the physical memory of the computer.

14. Implicit heap storage recovery eliminates the creation of dangling pointers through explicit deallocation operations, such as \texttt{delete}. The disadvantage of implicit heap storage recovery is the execution time cost of doing the recovery, often when it is not even necessary (there is no shortage of heap storage).

Chapter 7

Problem Set:
1. Suppose Type1 is a subrange of Integer. It may be useful for the difference between Type1 and Integer to be ignored by the compiler in an expression.

7. An expression such as \( a + \text{fun}(b) \), as described on page 300.

8. Consider the integer expression \( A + B + C \). Suppose the values of \( A, B, \) and \( C \) are 20,000, 25,000, and -20,000, respectively. Further suppose that the machine has a maximum integer value of 32,767. If the first addition is computed first, it will result in overflow. If the second addition is done first, the whole expression can be correctly computed.

9.

(a) \( ( ( a * b )^1 - 1 )^2 + c )^3 \)

(b) \( ( ( a * ( b - 1 )^1 )^2 / c )^3 \mod d )^4 \)

(c) \( ( ( a - b )^1 / c )^2 \& ( ( ( d * e )^3 / a )^4 - 3 )^5 )^6 \)

(d) \( ( ( - a )^1 \or ( c = d )^2 )^3 \and e )^4 \)

(e) \( ( a > b )^1 \xor ( c \or ( d <= 17 )^2 )^3 )^4 \)

(f) \( ( - ( a + b )^1 )^2 \)

10.

(a) \( ( a * ( b - ( 1 + c )^1 )^2 )^3 \)

(b) \( ( a * ( ( b - 1 )^2 / ( c \mod d )^1 )^3 )^4 \)

(c) \( ( ( a - b )^5 / ( c \& ( d * ( e / ( a - 3 )^1 )^2 )^3 )^4 )^6 \)

(d) \( ( - ( a \or ( c = ( d \and e )^1 )^2 )^3 )^4 \)

(e) \( ( a > ( \xor ( c \or ( d <= 17 )^1 )^2 )^3 )^4 \)

(f) \( ( - ( a + b )^1 )^2 \)

11. \(<\text{expr}> \ ? \ <\text{expr}> \or \ <\text{e1}> \ | \ <\text{expr}> \xor \ <\text{e1}> \ | \ <\text{e1}> \)

13. (a) (left -> right) sum1 is 46; sum2 is 48

(b) (right -> left) sum1 is 48; sum2 is 46

Chapter 8

Problem Set:

1. Three situations in which a combined counting and logical control loops are:

   a. A list of values is to be added to a \texttt{SUM}, but the loop is to be exited if \texttt{SUM} exceeds some prescribed value.

   b. A list of values is to be read into an array, where the reading is to terminate when either a prescribed number of values have been read or some special value is found in the list.

   c. The values stored in a linked list are to be moved to an array, where values are to be moved until the end of the linked list is found or the array is filled, whichever comes first.

4. Unique closing keywords on compound statements have the advantage of readability and the disadvantage of complicating the language by increasing the number of keywords.
8. The primary argument for using Boolean expressions exclusively as control expressions is the reliability that results from disallowing a wide range of types for this use. In C, for example, an expression of any type can appear as a control expression, so typing errors that result in references to variables of incorrect types are not detected by the compiler as errors.

Programming Exercises:

1.

(a) \[
\text{Do } K = (J + 13) / 27, 10 \\
\quad I = 3 \times (K + 1) - 1 \\
\text{End Do}
\]

(b) \[
\textbf{for } k \text{ \textbf{in} } (j + 13) / 27 .. 10 \textbf{ loop} \\
\quad i := 3 \times (k + 1) - 1; \\
\quad \text{end loop;}
\]

(c) \[
\textbf{for } (k = (j + 13) / 27; k <= 10; i = 3 \times (++k) - 1)
\]

2.

(a) \[
\text{Do } K = (J + 13.0) / 27.0, 10.0, 1.2 \\
\quad I = 3.0 \times (K + 1.2) - 1.0 \\
\text{End Do}
\]

(b) \[
\textbf{while } (k <= 10.0) \textbf{ loop} \\
\quad i := 3.0 \times (k + 1.2) - 1.0; \\
\quad k := k + 1.2; \\
\quad \text{end loop;}
\]

(c) \[
\textbf{for } (k = (j + 13.0) / 27.0; k <= 10.0; \\
\quad k = k + 1.2, i = 3.0 \times k - 1)
\]

3.

(a) Select Case \( k \)

Case \( 1, 2 \)

\( J = 2 \times K - 1 \)
Case (3, 5)
    \[ J = 3 \times K + 1 \]
Case (4)
    \[ J = 4 \times K - 1 \]
Case (6, 7, 8)
    \[ J = K - 2 \]
Case Default
    Print *, 'Error in Select, K = ', K
End Select

(b) case k is
    when 1 | 2 => j := 2 \times k - 1;
    when 3 | 5 => j := 3 \times k + 1;
    when 4 => j := 4 \times k - 1;
    when 6..8 => j := k - 2;
    when others =>
        Put ("Error in case, k =");
        Put (k);
        New_Line;
end case;

(c) switch (k)
{
    case 1: case 2:
        j = 2 \times k - 1;
        break;
    case 3: case 5:
        j = 3 \times k + 1;
        break;
}
case 4:
    j = 4 * k - 1;
    break;

case 6: case 7: case 8:
    j = k - 2;
    break;

default:
    printf("Error in switch, k =%d\n", k);

4. j = -3;

    key = j + 2;

    for (i = 0; i < 10; i++) {
        if ((key == 3) || (key == 2))
            j--;
        else if (key == 0)
            j += 2;
        else j = 0;
        if (j > 0)
            break;
        else j = 3 - i;
    }

5. (C)

    for (i = 1; i <= n; i++) {
        flag = 1;

        for (j = 1; j <= n; j++)
            if (x[i][j] <> 0) {
                flag = 0;
            }
break;
}

if (flag == 1) {
    printf("First all-zero row is: %d\n", i);
    break;
}
}

(Ada)

for I in 1..N loop
    Flag := true;
    for J in 1..N loop
        if X(I, J) /= 0 then
            Flag := false;
            exit;
        end if;
    end loop;
    if Flag = true then
        Put("First all-zero row is: ");
        Put(I);
        Skip_Line;
        exit;
    end if;
end loop;

Chapter 9
**Problem Set:**

2. The main advantage of this method is the fast accesses to formal parameters in subprograms. The disadvantages are that recursion is rarely useful when values cannot be passed, and also that a number of problems, such as aliasing, occur with the method.

4. This can be done in both Java and C#, using a static (or class) data member for the page number.

5. Assume the calls are not accumulative; that is, they are always called with the initialized values of the variables, so their effects are not accumulative.

   a. 2, 1, 3, 5, 7, 9   b. 1, 2, 3, 5, 7, 9   c. 1, 2, 3, 5, 7, 9
   2, 1, 3, 5, 7, 9   2, 3, 1, 5, 7, 9   2, 3, 1, 5, 7, 9
   2, 1, 3, 5, 7, 9   5, 1, 3, 2, 7, 9   5, 1, 3, 2, 7, 9 (unless the addresses of the actual parameters are recomputed on return, in which case there will be an index range error.)

6. It is rather weak, but one could argue that having both adds complexity to the language without sufficient increase in writability.

stack
4. One very simple alternative is to assign integer values to all variable names used in the program. Then the integer values could be used in the activation records, and the comparisons would be between integer values, which are much faster than string comparisons.

5. Following the hint stated with the question, the target of every goto in a program could be represented as an address and a nesting_depth, where the nesting_depth is the difference between the nesting level of the procedure that contains the goto and that of the procedure containing the target. Then, when a goto is executed, the static chain is followed by the number of links indicated in the nesting_depth of the goto target. The stack top pointer is reset to the top of the activation record at the end of the chain.

6. Including two static links would reduce the access time to nonlocals that are defined in scopes two steps away to be equal to that for nonlocals that are one step away. Overall, because most nonlocal references are relatively close, this could significantly increase the execution efficiency of many programs.

Chapter 11

Problem Set:

2. The problem with this is that the user is given access to the stack through the returned value of the "top" function. For example, if \( p \) is a pointer to objects of the type stored in the stack, we could have:

\[
\begin{align*}
p &= \text{top}(\text{stack1}); \\
*p &= 42;
\end{align*}
\]

These statements access the stack directly, which violates the principle of a data abstraction.
Chapter 12

Problem Set:

1. In C++, a method can only be dynamically bound if all of its ancestors are marked *virtual*. By default, all method binding is static. In Java, method binding is dynamic by default. Static binding only occurs if the method is marked *final*, which means it cannot be overridden.

3. C++ has extensive access controls to its class entities. Individual entities can be marked *public*, *private*, or *protected*, and the derivation process itself can impose further access controls by being *private*. Ada, on the other hand, has no way to restrict inheritance of entities (other than through child libraries, which this book does not describe), and no access controls for the derivation process.

Chapter 13

Problem Set:

1. Competition synchronization is not necessary when no actual concurrency takes place simply because there can be no concurrent contention for shared resources. Two nonconcurrent processes cannot arrive at a resource at the same time.

2. When deadlock occurs, assuming that only two program units are causing the deadlock, one of the involved program units should be gracefully terminated, thereby allowed the other to continue.

3. The main problem with busy waiting is that machine cycles are wasted in the process.

4. Deadlock would occur if the *release(access)* were replaced by a *wait(access)* in the consumer process, because instead of relinquishing access control, the consumer would wait for control that it already had.

6. Sequence 1:

   A fetches the value of BUF_SIZE (6)
   A adds 2 to the value (8)
   A puts 8 in BUF_SIZE
   B fetches the value of BUF_SIZE (8)
   B subtracts 1 (7)
   B put 7 in BUF_SIZE
   BUF_SIZE = 7

   Sequence 2:

   A fetches the value of BUF_SIZE (6)
   B fetches the value of BUF_SIZE (6)
   A adds 2 (8)
   B subtracts 1 (5)
   A puts 8 in BUF_SIZE
B puts 5 in BUF_SIZE
BUF_SIZE = 5

Sequence 3:  
A fetches the value of BUF_SIZE (6)  
B fetches the value of BUF_SIZE (6)  
A adds 2 (8)  
B subtracts 1 (5)  
B puts 5 in BUF_SIZE  
A puts 8 in BUF_SIZE  
BUF_SIZE = 8

Many other sequences are possible, but all produce the values 5, 7, or 8.

Chapter 14

Problem Set:

5. There are several advantages of a linguistic mechanism for handling exceptions, such as that found in Ada, over simply using a flag error parameter in all subprograms. One advantage is that the code to test the flag after every call is eliminated. Such testing makes programs longer and harder to read. Another advantage is that exceptions can be propagated farther than one level of control in a uniform and implicit way. Finally, there is the advantage that all programs use a uniform method for dealing with unusual circumstances, leading to enhanced readability.

6. There are several disadvantages of sending error handling subprograms to other subprograms. One is that it may be necessary to send several error handlers to some subprograms, greatly complicating both the writing and execution of calls. Another is that there is no method of propagating exceptions, meaning that they must all be handled locally. This complicates exception handling, because it requires more attention to handling in more places.

Chapter 15

Problem Set:

6. y returns the given list with leading elements removed up to but not including the first occurrence of the first given parameter.

7. x returns the number of non-NIL atoms in the given list.

Programming Exercises:
5. (DEFINE (deleteall atm lst)
   
   (COND
   
   ((NULL? lst) '())
   
   ((EQ? atm (CAR lst)) (deleteall atm (CDR lst)))
   
   (ELSE (CONS (CAR lst) (deleteall atm (CDR lst)))))
)

7. (DEFINE (deleteall atm lst)
   
   (COND
   
   ((NULL? lst) '())
   
   ((NOT (LIST? (CAR lst)))
   
   (COND
   
   ((EQ? atm (CAR lst)) (deleteall atm (CDR lst)))
   
   (ELSE (CONS (CAR lst) (deleteall atm (CDR lst)))))
   
   (ELSE (CONS (deleteall atm (CAR lst))
   
   (deleteall atm (CDR lst))))))
)

9. (DEFINE (reverse lis)
   
   (COND
   
   ((NULL? lis) '())
   
   (ELSE (APPEND (reverse (CDR lis)) (CONS (CAR lis) () ))))
)

Chapter 16
Problem Set:

1. Ada variables are statically bound to types. Prolog variables are bound to types only when they are bound to values. These bindings take place during execution and are temporary.

2. On a single processor machine, the resolution process takes place on the rule base, one rule at a time, starting with the first rule, and progressing toward the last until a match is found. Because the process on each rule is independent of the process on the other rules, separate processors could concurrently operate on separate rules. When any of the processors finds a match, all resolution processing could terminate.

6. The list processing capabilities of Scheme and Prolog are similar in that they both treat lists as consisting of two parts, head and tail, and in that they use recursion to traverse and process lists.

7. The list processing capabilities of Scheme and Prolog are different in that Scheme relies on the primitive functions CAR, CDR, and CONS to build and dismantle lists, whereas with Prolog these functions are not necessary.

Programming Exercises:

2. intersect([], X, []).
   intersect([X | R], Y, [X | Z] :-
     member(X, Y), !,
     intersect(R, Y, Z).
   intersect([X | R], Y, Z) :- intersect(R, Y, Z).

Note: this code assumes that the two lists, X and Y, contain no duplicate elements.

3. union([], X, X).
   union([X | R], Y, Z) :- member(X, Y), !, union(R, Y, Z).
   union([X | R], Y, [X | Z]) :- union(R, Y, Z).
